-

- Homework #4 is due next week.
- Please read Chapter 14 of the textbook. If you don't have these chapters, email me.

▲圖 ▶ ▲ 国 ▶ ▲ 国 ▶ …

æ

- In extensive games with imperfect information, players are uncertain about what actions have been chosen in the past.
- A player knows that he is at a particular *information set* (i.e. a set of histories), but does not know exactly which history he is at.
- A player still has *beliefs* about which history in his information set is more likely. We use a probability distribution to model beliefs.
- We want a player's belief at every information set to match the true probability distribution, given the behavioral strategies of all players.
- That is, a player's belief should match the conditional probabilities of the histories, conditional on reaching the information set.
- If an information set is reached with probability 0, any beliefs are consistent.

(4回) (注) (注) (注) (三)

- An *belief system* is a list of beliefs at every information set.
- A *behavioral strategy profile* is a list of behavioral (i.e. mixed) strategies at every information set.
- A *weak sequential equilibrium* is a pair consisting of a belief system and a behavioral strategy profile, such that:
 - Beliefs are consistent, given the behavioral strategies
 - Strategies are optimal, given beliefs
- No player has an incentive to deviate, and no player has any reason to change his beliefs.

・ 同 ト ・ ヨ ト ・ ヨ ト

- In many situations, Player 1 may know something that Player 2 does not, which would affect Player 2's choice if he knew. For example:
 - When you buy an item from a seller, the seller knows the item's quality, but you do not.
 - When a firm hires an employee, the employee knows his skill level, but the firm does not.
 - When two people get into a competition, each person knows how strong he is, but the other person does not.
- This is called a situation with *asymmetric information*.

・ 同 ト ・ ヨ ト ・ ヨ ト …

Ch. 10.5: Signaling Games

- We can model this kind of situation by assuming there are two (or more) types of Player 1, which is chosen by Nature with a known probability distribution.
- Suppose there are two types of Player 1, the "high" type H, and the "low" type L. H-types are more preferable to Player 2.
- Supose Player 1 is a *H*-type. Then he would like to somehow let Player 2 know that he is a *H*-type.
- On the other hand, suppose Player 2 is a L-type. Then he would like to imitate the H-type, and make Player 2 believe that he is type H.
- ► A *H*-type Player 1 could simply say that he is *H*-type, but why should Player 2 believe it? A *L*-type player could do exactly the same thing.
- However, if there was some test that L-types found more costly to pass than H-types, then perhaps L-types would rationally choose not to take the test at all.

・ロン ・回 と ・ ヨ と ・ ヨ と

- These games are called *signaling games*.
- At the beginning, Nature chooses Player 1's type according to a known distribution.
- Player 1 can choose to send a *costly signal* that Player 2 observes.
- Player 2 then chooses his action, taking Player 1's choice into account.
- In a pooling equilibrium, H and L types of Player 1 behave the same way, and Player 2 cannot distinguish between them.
- ▶ In a *separating equilibrium*, *H* and *L* types behave differently, and Player 2 can tell them apart.

(ロ) (同) (E) (E) (E)

- Consider this variant of the Entry Game.
- ► There are two types of *Challenger*, *Strong* and *Weak*, which occur with probabilities p and 1 p.
- The *Challenger* knows his type, but the *Incumbent* does not.
- Challenger can choose to be Ready or Unready for competition. Choosing Ready is more costly for a Weak-type.
- The *Incumbent* can choose to fight, *F*, or acquiesce, *A*.
- Incumbent prefers to fight a Weak challenger, but prefers to acquiesce to a Strong challenger.
- If the *Incumbent* chooses to fight, both types of challenger suffer the same cost.

- The start of the game is in the center.
- The first number is the *Challenger*'s payoff. *Challenger*'s payoff is 5 if *Incumbent* chooses *A*.
- Cost of *Ready* is 1 for *Strong*-type, 3 for *Weak*-type.

- Challenger has two information sets: {Strong} and {Weak}.
- Incumbent has two information sets: {(Strong, Ready), (Weak, Ready)} and {(Strong, Unready), (Weak, Unready)}.
- Each player has 2 actions at each information set, so a total of 4 pure strategies.

< ∃ >

- Challenger's pure strategies: RR, RU, UR, UU
- Incumbent's pure strategies:
 (A|R, A|U), (A|R, F|U), (F|R, A|U), (F|R, F|U) where the notation
 (A|R, A|U) means: choose A conditional on R, choose A conditional on U
- Suppose 0 Incumbent's information sets are reached with positive probability. Let's calculate the expected payoffs to pure strategy profiles.

- For the strategy profile (*RR*, (*A*|*R*, *A*|*U*)), the outcome will be (*Strong*, *R*, *A*) with probability *p*, and (*Weak*, *R*, *A*) with probability (1 − *p*).
- ► Expected payoffs are (4p+2(1-p), 2p).

→ ∃ >

- For the strategy profile (RU, (A|R, A|U)), the outcome will be (Strong, R, A) with probability p, and (Weak, U, A) with probability (1 − p).
- ► Expected payoffs are (4p + 5(1 p), 2p).

→ ∃ >

	UR	UU	
A R, A U	p(5,2) + (1-p)(2,0)	p(5,2) + (1-p)(5,0)	
A R, F U	p(3,-1) + (1-p)(2,0)	p(3,-1) + (1-p)(3,1)	
F R, A U	p(5,2) + (1-p)(0,1)	p(5,2) + (1-p)(5,0)	
F R,F U	p(3,-1) + (1-p)(0,1)	p(3,-1) + (1-p)(3,1)	

< 67 ▶

	A R, A U	A R, F U	F R, A U	F R, F U
RR	3,1	3,1	1,0	1,0
RU	4.5, 1	3.5, 1.5	3.5, -0.5	2.5, 0
UR	3.5, 1	2.5, -0.5	2.5, 1.5	1.5, 0
UU	5, 1	3, 0	5, 1	3, 0

► The NE are: (RU, (A|R, F|U)), (UU, (A|R, A|U)), and (UU, F|R, A|U)). Let's go through each of these and see which ones can be part of a WSE.

回 と く ヨ と く ヨ と …

- Consider the NE (RU, (A|R, F|U)).
- The beliefs at *Incumbent*'s information set after R must be (1,0) (probability 1 on *Strong*) since *Challenger*'s strategy will only choose R if Nature chose *Strong*.
- The beliefs at *Incumbent*'s information set after U must be (0,1) (probability 0 on *Strong*).
- The actions specified for *Incumbent* at this NE are clearly optimal given these beliefs, so this is a WSE.

・ 同 ト ・ ヨ ト ・ ヨ ト

Check if NE is a WSE

- Consider the NE (UU, (A|R, A|U)).
- The beliefs at *Incumbent*'s information set after U must be (p, 1-p) = (0.5, 0.5).
- Clearly, *Challenger*'s actions specified by this NE are optimal at this information set, since it is a NE.
- ▶ The information set after *R* is reached with zero probability, so any beliefs are consistent.
- ▶ Denote the beliefs at this information set as (q, 1 q), where q is the probability on Strong.
- We want to find the range of q that makes A optimal, i.e. $E(A) \ge E(F)$, which is true if:

$$q2 + (1-q)0 \ge q(-1) + (1-q)1$$

• or if $q \ge \frac{1}{4}$.

(日本)(日本)(日本)(日本)

Check if NE is a WSE

- Consider the NE (UU, F|R, A|U)).
- For the information set after *U*, everything is the same as in the previous case.
- The information set after *R* is reached with zero probability, so any beliefs are consistent.
- ▶ Denote the beliefs at this information set as (q, 1 q), where q is the probability on Strong.
- We want to find the range of q that makes F optimal, i.e. $E(A) \le E(F)$, which is true if:

$$q^2 + (1-q)^0 \le q(-1) + (1-q)^1$$

• or if $q \leq \frac{1}{4}$.

マボン イラン イラン 一日

Separating & Pooling Equilibria

- ▶ There is one separating equilibrium: (RU, (A|R, F|U)), and Incumbent's beliefs are (1,0) after R and (0,1) after U.
- In a separating equilibrium the different types of Player 1 choose different actions, so Player 2 knows which type they are by their choice.
- ► There is a set of *pooling* equilibria: (UU, (A|R, A|U)) and (UU, F|R, A|U)).
- ▶ In both of these cases, the information set after *R* is reached with zero probability, so any beliefs are consistent.
- If the beliefs are such that A to be optimal, then the WSE is (UU, (A|R, A|U)); otherwise, it is (UU, F|R, A|U)).
- In a pooling equilibrium, the different types of Player 1 behave the same way, and Player 2 cannot distinguish them.

(日) (四) (王) (王) (王)

- Why do students obtain a college degree?
- One reason is that the knowledge they gain in college will increase their skills and abilities.
- However, there is another possible reason: perhaps students use degrees to *differentiate* themselves from other students when applying for jobs.
- > This can hold even if the degree itself does not increase ability.
- We model this as a signaling game.

・ 回 ト ・ ヨ ト ・ ヨ ト ・

- Suppose the ability level of a worker can be measured by a single number
- There are two types of workers: "high" and "low"-ability workers, denoted H and L, with L < H.</p>
- Type is known to the workers, but cannot be directly observed by employers.
- Workers can choose to obtain some amount of education, which has no effect on ability, but costs less for the *H*-type worker.

・回 ・ ・ ヨ ・ ・ ヨ ・

- The sequence of the game is as follows:
 - Chance chooses the type of the worker at random; the probability of H is p.
 - The worker, who knows his type, chooses an amount of education e ≥ 0. The cost of education is different according to type; for a L-type worker, the cost is e/L; for a H-type worker, it is e/H.
 - Two firms observe the worker's choice of e (but not his type), and simultaneously offer two wages, w₁ and w₂.
 - The worker chooses one of the wage offers and works for that firm. The worker's payoff is his wage minus the cost of education. The firm that hires the worker gets a payoff of the worker's ability, minus the wage. The other firm gets a payoff of 0.

(ロ) (同) (E) (E) (E)

Game Tree

◆□ > ◆□ > ◆臣 > ◆臣 > ─ 臣 ─ のへで

- We claim there is a weak sequential equilibrium in which a *H*-type worker chooses a positive amount of education, and a *L*-type worker chooses zero education.
- Consider this assessment (i.e. beliefs plus strategies), where e* is a positive number (to be determined):
 - Worker's strategy: Type H chooses e = e* and type L chooses e = 0. After observing w1, w2, both types choose the highest offer if w1, w2 are different, and firm 1 if they are the same.
 - Firms' belief: Each firm believes that a worker is type H if he chooses e = e*, and type L otherwise.
 - Firms' strategies: Each firm offers the wage H to a worker who chooses e = e*, and L to a worker who chooses any other value of e.

(ロ) (同) (E) (E) (E)

Finding WSE

- Let's check that the conditions for consistency of beliefs and optimality of strategies are satisfied.
 - Consistency of beliefs: take the worker's strategy as given.
 - The only information sets of the firm that are reached with positive probability are after e = 0 and e = e*; at all the rest, the firms' beliefs may be anything.
 - At the information set after e = 0, the only correct belief is P(H|e = 0) = 0.
 - At the information set after $e = e^*$, the only correct belief is $P(H|e = e^*) = 1$. So these beliefs are consistent.
 - Optimality of firm's strategy: Each firm's payoff is 0, given its beliefs and strategy.
 - If a firm deviates by offering a higher wage, it will make a negative profit.
 - If it deviates by offering a lower wage, it gets a payoff of 0 since the worker will choose the other firm. So, there is no incentive to deviate.

・ロン ・回 と ・ ヨ と ・ ヨ と

- Optimality of worker's strategy: In the last subgame, the worker's strategy of choosing the higher wage is clearly optimal. Let's consider the worker's choice of e:
 - Type *H*: If the worker maintains the strategy and chooses $e = e^*$, he will get a wage offer of *H* and his payoff will be $H \frac{e^*}{H}$.
 - If the worker deviates and chooses any other *e*, he will get a wage offer of *L* and his payoff will be $L \frac{e}{H}$.
 - The highest possible payoff when deviating is when e = 0, which gives a payoff of *L*.
 - Therefore, in order for our hypothetical equilibrium to be optimal, we need $H \frac{e^*}{H} \ge L$, or

$$e^* \leq H(H-L)$$

(ロ) (同) (E) (E) (E)

- Type L: If the worker maintains the strategy and chooses e = 0, he will get a wage offer of L and his payoff will be L.
- If the worker deviates and chooses anything but e^* , he still gets a wage offer of L and a lower payoff of $L \frac{e}{l}$.
- ▶ If the worker deviates and chooses e^* (i.e. imitates a *H*-type) then he gets a wage offer of *H*, for a total payoff of $H \frac{e^*}{I}$.
- For our hypothetical equilibrium to be optimal, we need $L \ge H \frac{e^*}{L}$ or

 $e^* \ge L(H-L)$

 Combining these requirements, the condition for this equilibrium to be optimal is:

$$L(H-L) \le e^* \le H(H-L)$$

- If this is satisfied, then separating equilibria exist in which *H*-type workers can be distinguished from *L*-type workers by their choice of *e*.
- This is not the only type of equilibrium that exists: there may also exist pooling equilibria, given the same values of H and L, in which both types of workers choose the same amount of education.

伺下 イヨト イヨト

Chapter 14: Repeated Prisoner's Dilemma

- Let's recall the Prisoner's Dilemma.
- Here, we are labeling the actions for each player as *Cooperate* or *Defect*.
- ► As we have seen, this game has a single Nash equilibrium (D, D), where both players choose Defect.
- In real life, however, people frequently manage to sustain cooperation, in contrast to the theoretical prediction of the Prisoner's Dilemma model.

伺 ト イヨト イヨト

Chapter 14: Repeated Prisoner's Dilemma

- One possible explanation for this is that playing Prisoner's Dilemma only once misses a key feature of the real world: that agents interact *repeatedly*.
- If agents know they will interact again in the future, defecting in one time period may be punished by reciprocal defecting in the future.
- Agents can develop a reputation for cooperating or defecting.
- We will study a specific case of repeated interaction, where the same agents meet in several periods and play the Prisoner's Dilemma in each period.
- In order to analyze this situation, we will need to define what a strategy is, and what preferences are for games played in several periods.
